

### 8.1 CPA-secure encryption

#### 8.1.a $\Sigma'$ CPA\$-secure?

We consider the following distinguisher:

**Distinguisher A**  
**pick**  $k \in \{0, 1\}^\lambda$   
**pick**  $m \in \{0, 1\}^\lambda$   
 $y = \Sigma'(k, m)$   
**return**  $\text{first two bits of } y \stackrel{?}{=} 00$

First we will pick  $k$  and  $m$  at random. Then the return value of  $\Sigma'$  is checked whether the two starting bits are both 0 or not.

It is obvious that for  $L_{CPA-real}^{\Sigma'}$  the distinguisher will always output 1. For  $L_{CPA-rand}^{\Sigma'}$  the distinguisher will only output 1 if the random algorithm outputs a bit-string with the first two bits being 0. The probability for this will be  $\frac{1}{4}$ .

For the advantage we will then get:

$$\begin{aligned} \text{Bias}(A) &= | \Pr(A \diamond L_{CPA-real}^{\Sigma'}) - \Pr(A \diamond L_{CPA-rand}^{\Sigma'}) | \\ &= | 1 - \frac{1}{4} | \\ &= \frac{3}{4} \neq 0 \end{aligned}$$

Therefore  $\Sigma'$  is not CPA\$-secure.

#### 8.1.b $\Sigma'$ CPA-secure?

1. We will show that  $\Sigma' \diamond \Sigma(k, m_L)$  is indistinguishable from  $\Sigma' \diamond \Sigma(k, m_R)$ :

**$L_{CPA-L}^{\Sigma'}$**   
**pick**  $k \in \{0, 1\}^\lambda$   
  
EAVESDROP( $m_L, m_R$ )  
 if  $|m_L| \neq |m_R|$   
 then return ERROR  
 $c := 00 \parallel \Sigma.\text{Enc}(k, m_L)$   
**return**  $c$

This is our starting library  $L_{CPA-L}^{\Sigma'}$ .

**$L_{CPA}^{\Sigma'}$**   
**pick**  $k \in \{0, 1\}^\lambda$   
  
EAVESDROP( $m_L, m_R$ )  
 if  $|m_L| \neq |m_R|$   
 then return ERROR  
 $c := 00 \parallel \Sigma.\text{Enc}(k, (m_L, m_R))$   
**return**  $c$

$\diamond$

**$L_{CPA-L}^{\Sigma}$**   
 $\text{Enc}(k, (m_L, m_R))$   
 if  $|m_L| \neq |m_R|$   
 then return ERROR  
 $c := \Sigma.\text{Enc}(k, m_L)$   
**return**  $c$

With adding  $L_{CPA-L}^{\Sigma}$  we create a hybrid-library.

$L_{CPA}^{\Sigma'}$   
**pick**  $k \in \{0, 1\}^\lambda$   
EAVESDROP( $m_L, m_R$ )  
 if  $|m_L| \neq |m_R|$   
 then return ERROR  
 $c := 00 \parallel \Sigma.Enc(k, (m_L, m_R))$   
**return**  $c$

◇

$L_{CPA-R}^{\Sigma}$   
Enc( $k, (m_L, m_R)$ )  
 if  $|m_L| \neq |m_R|$   
 then return ERROR  
 $c := \Sigma.Enc(k, m_R)$   
**return**  $c$

Because we know that  $\Sigma$  has CPA\$-security (especially also CPA-security)  $L_{CPA-L}^{\Sigma} \approx L_{CPA-R}^{\Sigma}$

$L_{CPA-R}^{\Sigma'}$   
**pick**  $k \in \{0, 1\}^\lambda$   
EAVESDROP( $m_L, m_R$ )  
 if  $|m_L| \neq |m_R|$   
 then return ERROR  
 $c := 00 \parallel \Sigma.Enc(k, m_R)$   
**return**  $c$

Therefore we can inline this subroutine to end with the library  $L_{CPA-R}^{\Sigma'}$ . Therefore we showed that  $L_{CPA-L}^{\Sigma'} \approx L_{CPA-R}^{\Sigma'}$ .

## 8.2 From a PRP to CPA-secure encryption

### 8.2.1 Corresponding Decoder

#### 8.2.1.a

$Enc(k, m)$  :  
 $r \leftarrow \{0, 1\}^\lambda$   
 $z := F(k, m) \oplus r$   
**return**  $(r, z)$

$Dec(r, z)$  :  
 $c = z \oplus r$   
 $m' = F^{-1}(c)$   
**return**  $m'$

#### 8.2.1.b

$Enc(k, m)$  :  
 $r \leftarrow \{0, 1\}^\lambda$   
 $s := r \oplus m$   
 $x := F(k, r)$   
**return**  $(s, x)$

$Dec(r, z)$  :  
 $r = F^{-1}(x)$   
 $m' = r \oplus s$   
**return**  $m'$

#### 8.2.1.c

$Enc(k, m)$  :  
 $s_1 \leftarrow \{0, 1\}^\lambda$   
 $s_2 := s_1 \oplus m$   
 $x := F(k, s_1)$   
 $y := F(k, s_2)$   
**return**  $(x, y)$

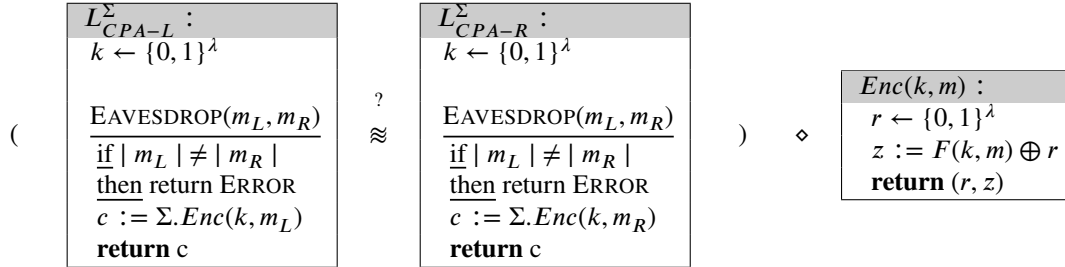

$Dec(r, z)$  :  
 $s_1 = F^{-1}(x)$   
 $s_2 = F^{-1}(y)$   
 $m' = s_2 \oplus s_1$   
**return**  $m'$

## 8.2.2 CPA-secure?

### 8.2.2.a

No, it is not *CPA-secure*, because:

**Proof:**

We will consider the following distinguisher:

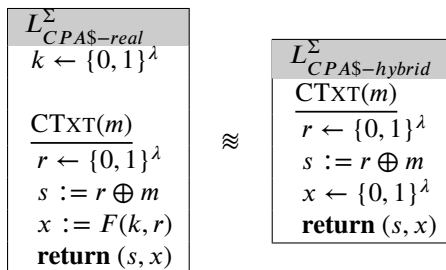

First we will pick two messages  $x$  and  $y$  at random. Then the return values of  $\text{EAVESDROP}(m_L, m_R)$  are fetched. In the end the XOR-step which the encoder has done, will be reversed by using the return values. The distinguisher will therefore output whether both  $F(k, m)$  have returned the same value.

It is obvious that if the  $L_{CPA-L}^\Sigma$  is used the adversary will output 1 because in both cases  $F(k, x)$  is returned. If the  $L_{CPA-R}^\Sigma$  is used one will output  $F(k, x)$  and the other one will output  $F(k, y)$  which will not be the same and therefore the output value of A will be 0. So the adversary can distinguish between  $L_{CPA-L}^\Sigma$  and  $L_{CPA-R}^\Sigma$  and therefore this encoder is not *CPA-secure*.

### 8.2.2.b

Yes, it is *CPA-secure*, because:

**Proof (We will show that the encoder has *CPA\$-security* and is therefore also *CPA-secure*):**

Because we know that  $F$  is a secure PRP/PRF we can inline the subrou-tine of a random PRP/PRF.

$L_{CPA\$-hybrid}^\Sigma$
$CTXT(m)$
$r \leftarrow \{0, 1\}^\lambda$
$s := r \oplus m$
$x \leftarrow \{0, 1\}^\lambda$
<b>return</b> $(s, x)$

$\approx$

$L_{CPA\$-hybrid}^\Sigma$
$CTXT(m)$
$s \leftarrow \{0, 1\}^\lambda$
$x \leftarrow \{0, 1\}^\lambda$
<b>return</b> $(s, x)$

Because "XORing" a random bitstring with the message bitstring is also the same as generating a random bitstring, we can change this in the hybrid.

$L_{CPA\$-hybrid}^\Sigma$
$CTXT(m)$
$s \leftarrow \{0, 1\}^\lambda$
$x \leftarrow \{0, 1\}^\lambda$
<b>return</b> $(s, x)$

$\approx$

$L_{CPA\$-rand}^\Sigma$
$CTXT(m)$
$r \leftarrow (\{0, 1\}^\lambda)^2$
<b>return</b> $r$

Because  $s$  and  $x$  are making up a pair which is in  $C$  we can inline such a subroutine to end up with  $L_{CPA\$-rand}^\Sigma$ .

### 8.2.2.c

No, it is not *CPA-secure*, because if whether one of  $m_L$  and  $m_R$  is the 0-bit-string, the  $s_2$  bit string will be the same as the  $s_1$  bit string and therefore the return value  $x$  and  $y$  will be bitwise equal.

## 8.3 Modes of operation

### 8.3.1 CBC

It will affect the block which is corresponding with the encrypted block with the error as well as all the following blocks.

### 8.3.2 OFB

It will only affect the block which is corresponding with the encrypted block with the error.

### 8.3.3 CTR

It will only affect the block which is corresponding with the encrypted block with the error.
