

# Cryptography

## Organization:

- 09. Oct. cancelled
- 11. Oct. (14:00-17:00) replacement
- 23. Oct. cancelled

## 2. Provable Security

### One-time pad:

- not practical
- information-theoretically secure
  - too strong
- illustrative

### Practical cryptosystems

- computationally secure

## 2.1 Formalization of Encryption

### 2.1.1 Syntax

#### Definition:

A symmetric-key cryptosystem  $\Sigma$  consists of 3 algorithms (SKE):

- $\text{KeyGen}() \rightarrow k$ , randomized,  $k \in K$
- $\text{Enc}(k,m) \rightarrow c$ ,  $m \in M$ ,  $c \in C$  (might be randomized)
- $\text{Dec}(k,c) \rightarrow m$ , deterministic

$\Sigma = (\Sigma.\text{KeyGen}, \Sigma.\text{Enc}, \Sigma.\text{Dec}, \Sigma.K, \dots)$

### 2.1.2 Correctness

Definition:

A cryptosystem  $\Sigma$  is correct if  $\forall k \in K, \forall m \in M$ :

$$P[Dec(k, Enc(k, m)) = m] = 1$$

Example:

$Enc(k, m) \rightarrow m$

$Dec(k, c) \rightarrow c$

$\Rightarrow$  correct but totally insecure

### 2.1.3 Terminology in distributed systems:

**Liveness : correctness**

"something good eventually happens"

**Safety : security**

"nothing bad has happened"

### 2.1.4 Security

Eavesdrop()-experiment from One-time pad (OTP)

- too specific to OTP

**Candidate sec.def. A (attempt 2)**

$\Sigma$  is secure if  $\forall m \in M$ , the output of Eavesdrop(m) is a random variable with uniform distribution over  $C$ :

$$\begin{array}{l} \text{Eavesdrop}(m \in M): \\ \hline k \leftarrow \text{KeyGen}() \\ c \leftarrow \text{Enc}(k, m) \\ \text{return } c \end{array}$$

**Candidate sec.def. B (attempt 3)**

$\Sigma$  is secure if  $\forall m \in M$ , the following functions produce the same random variable:

$$\begin{array}{l} \text{"real" Eavesdrop}(m \in M): \\ \hline k \leftarrow \text{KeyGen}() \\ c \leftarrow \text{Enc}(k, m) \\ \text{return } c \end{array}$$
$$\begin{array}{l} \text{"ideal/fake" Eavesdrop}(m \in M): \\ \hline c \leftarrow C \\ \text{return } c \end{array}$$

Definition B used indistinguishability of distributions

Move towards a definition with an adversary A (distinguishing algorithm)

$$P[A \text{ with } B\text{-left} \rightarrow 1] = P[A \text{ with } B\text{-right} \rightarrow 1]$$

$$A \text{ outputs } b \in \{0, 1\}$$

#### Candidate sec.def. C (attempt 4)

$\Sigma$  is secure if  $\forall$  alg. A, running A With the left or right experiment of Attempt-B outputs 1 is the same.

*How secure/useful is this?*

$K = M = \{0, 1\}^\lambda$

$\text{Enc}(k, m) \rightarrow m \oplus k \parallel m \oplus k$

$\text{Dec}(k, c) \rightarrow c_1 \parallel c_2 = c$ , return  $c_1 \oplus k$

That example shows that Attempt-C was too strong!

#### Candidate sec.def. D (attempt 4)

$\Sigma$  is secure if  $\forall$  alg. A and  $\forall m_L, m_R \in M$  running with left or right implementation of Eavesdrop, A outputs 1 with equal probability.

$$\frac{\text{Eavesdrop}(m_L, m_R)}{k \leftarrow \text{KeyGen}() \\ c \leftarrow \text{Enc}(k, m_L) \\ \text{return } c}$$

$$\frac{\text{Eavesdrop}(m_L, m_R)}{k \leftarrow \text{KeyGen}() \\ c \leftarrow \text{Enc}(k, m_R) \\ \text{return } c}$$

$\rightsquigarrow$  *chosen-plaintext attack*

## 2.2 Defining provable security

Definition:

A Library L is a collection of functions and static (private) variables.

The interface are its functions and their arguments and types.

Definition:

Running a program P with Library L is denoted  $P \diamond L$  ("P linked to L").

$$P \rightarrow 1$$

$$P \diamond L \rightarrow 1$$

L  
 $s \leftarrow \{0, 1\}^\lambda$   
Guess(x):  
 return  $x \stackrel{?}{=} s$

A:  
 repeat  
 $x \leftarrow \{0, 1\}^\lambda$   
 until  $\text{Guess}(x) = \text{TRUE}$   
 return  $x$   
 $P[A \Diamond L \rightarrow z] \stackrel{?}{=} 2^{-\lambda}$  for any  $z \in \{0, 1\}^\lambda$

B:  
 $c \leftarrow \{0, 1\}^\lambda$   
 return  $\text{Guess}(x)$   
 $P[B \Diamond L \rightarrow \text{TRUE}] = 2^{-\lambda}$

### 2.2.1 Two Libraries with same VO behaviour

Definition:

Two Libraries  $L_L$  and  $L_R$  are exchangeable written:

$$L_L \equiv L_R,$$

if for all distinguishable alg. A:

$$P[A \Diamond L_L \rightarrow 1] = P[A \Diamond L_R \rightarrow 1]$$

IMPORTANT:

- A interacts with L only via the interface
- No side-channels

### 2.2.2 Two Libraries $L_{eager} \equiv L_{lazy}$

$L_{eager}$   
for  $x \in X$  do  
 $T[x] \leftarrow \{0, 1\}^\lambda$

Get(x)  
 return  $T[x]$

$L_{lazy}$   
 $T[\bullet] = \perp$

Get(x)  
if  $T[x] = \perp$  then  
 $T[x] \leftarrow \{0, 1\}^\lambda$   
 return  $T[x]$

### 2.2.3 Security definition using libraries

Definition:

An encryption-scheme  $\Sigma$  has uniform ciphertxts if:

$$L_{ots\$-real} \equiv L_{ots\$-rand}$$

$L_{ots\$-real}$   
 $\text{CT} \times \text{T}(\text{m})$   
 $\overline{k \leftarrow \text{KeyGen}()}$   
 $c \leftarrow \text{Enc}(k, m)$   
 return c

$L_{ots\$-rand}$   
 $\text{CT} \times \text{T}(\text{m})$   
 $\overline{c \leftarrow \text{C}}$   
 return c

Definition:

An encryption-scheme  $\Sigma$  has one-time secrecy if:

$$L_{ots-left} \equiv L_{ots-right}$$

$L_{ots-left}$   
 $\text{Eavesdrop}(m_L, m_R)$   
 $\overline{k \leftarrow \text{KeyGen}()}$   
 $c \leftarrow \text{Enc}(k, m_L)$   
 return c

$L_{ots-right}$   
 $\text{Eavesdrop}(m_L, m_R)$   
 $\overline{k \leftarrow \text{KeyGen}()}$   
 $c \leftarrow \text{Enc}(k, m_R)$   
 return c
