### 1 Introduction - February 19, 2020

#### 1.1 Defining Dependable Systems

#### QUOTES:

A distributed system is a system where a computer of which you did not know it exists can prevent you from getting your job done. - Leslie LAMPORT

There is perhaps a market for maybe five computers in the world. - TJ WATSON

#### $FAULT \rightarrow ERROR \rightarrow FAILURE$

- Train delayed because of tree has fallen on the tracks
- Travelers reach destination too late
- Alice misses her exam

	FAULT	Error	FAILURE
Train:	Tree fallen	no train	delay for passengers
Journey:	Train delay	delay	reached destination 2h after intention
Exam:	arrival 2h late	missed time-slot	repeat exam

FAULT: cause of failure

ERROR: internal state of system, not according to specification

FAILURE: observable deviation of specification

#### FAULT examples:

- timing
- cables
- power supply
- messages lost
- data loss (solved with RAIDs)

#### 1.1.1 How to make systems tolerate faults

- PREVENTION
- TOLERANCE
  - Replication/Redundancy
  - Recovery
- REMOVAL
- FORECASTING/PREDICTION

 $SAFETY \neq SECURITY$ 

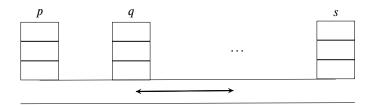

SAFETY is connected to loss of live/material due to accidents

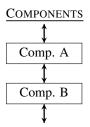

SECURITY is connected to malicious intent

#### 1.1.2 Defining distributed computation

Processes 
$$\Pi = \{p, q, r, s \dots\}$$
  
 $\mid \Pi \mid = N$ 

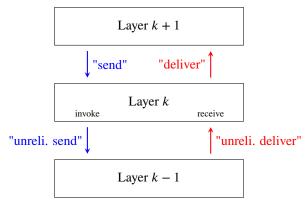

EVENTS for Component c:

$$\langle c, event \mid param_1, param_2 \dots \rangle$$
 
$$\frac{\text{upon } \langle c, ev_1 \mid param_1 \rangle \underline{\text{do}}}{\text{do something trigger } \langle b, domore \mid p \rangle}$$
 
$$\text{upon } \langle b, domore \mid p \rangle \underline{\text{do}}$$

#### 1.1.3 Layered modules

Events either travel:

- upwards (red): indication - downwards (blue): request

Events on a given layer may be:

- input events (IN)
- output events (OUT)

#### 1.1.4 Module Jobhandler

```
Events:
   Request: \langle jh, handle \mid job \rangle
   Indication: \langle jh, confirm \mid job \rangle
Properties:
   Every job submitted for handling is eventually confirmed.
Implementation (synchronized) JOBHANDLER
State
upon \langle jh, handle \mid job \rangle do
    "process job"
   trigger \langle jh, confirm \mid job \rangle
upon ...
upon ...
Implementation (asynchronized) JOBHANDLER
State
   \overline{bu}f \leftarrow \emptyset
upon \langle jh, handle \mid job \rangle \underline{do}
   \overline{buf} \leftarrow buf \cup \{job\}
   trigger \langle jh, confirm \mid job \rangle
upon buf \neq \emptyset do
   \overline{job} \leftarrow \text{some element of } buf
    "process job"
   buf \leftarrow buf \setminus \{job\}
```

#### 1.2 Concurrency and Replication in Distributed Systems

## **Distributed Algorithms**LECTURES

### 2 Models and Abstructions - February 26, 2020

#### 2.1 Processes and Protocols

- Set of Processes Π
  - $|\Pi| = N$
- A process is an automaton
- A protocol is a set of processes

#### 2.1.1 Execution

- Each computation step and every step of sending a message or receiving a message is an event
- An execution (history) is a sequence of all events of the processes as seen by a (hypothetical) global observer
- trace = execution

#### 2.1.2 Properties

Used for specifying the abstractions:

- Safety properties (something "bad" has not happened)

  If a property P has been violated in some execution E, then there exists a prefix E' of E such that in every extension of E', property P is violated
- Liveness properties (something "good" will happen in the future [EVENTUALLY]) Property P can be satisfied by some extension E of a given execution E

Safety or Liveness alone is not very useful. Only combination of both properties.

#### 2.1.3 Process Failures

A process consists of different modules - if one of them fails the entire thing fails at once.

#### **★** Crashes

- Omission failures (message sending and receiving events are omitted)
- Crash-Recovery Failure
  - store(-) operation to write to stable storage
  - upon recovery, one can restore(-) data from this stable storage
- Eavesdropping Fault

#### ★ Arbitrary Fault (Byzantine Fault)

#### 2.2 Cryptographic Abstraction

• Hash functions (SHA-256)

 $H: 0, 1^* \to \{0, 1\}^k$ 

- collision-free: difficult to find x, x' with  $x \neq x'$  and H(x) = H(x')
- Message-Authentication-Code (MAC) (HMAC-SHA256)
  - $authentication(p, q, m) \rightarrow a$
  - $verifyAuth(p, q, m, a) \rightarrow YES/NO$
- Digital Signatures (RSA, (EC)DSA)
  - $sign(p, m) \rightarrow s$
  - $verifySign(p, m, s) \rightarrow YES/NO$
  - ★ Correctness:

 $\forall m, p : verifySign(p, m, sign(p, m)) = YES$ 

★ Security:

 $\forall \overline{m, p, s}$ : verifySign(p, m, s) = No, unless p has executed  $sign(p, m) \rightarrow s$ 

#### 2.3 Communication Abstraction

Every process can send messages to every other process.

#### 2.3.1 Stubborn point-to-point links

#### **Events:**

 $\langle sl.send \mid q, m \rangle$  { send message m to process q  $\langle sl.deliver \mid p, m \rangle$  { deliver a received message m from process p

#### **Properties:**

Stubborn delivery:

If a process sends a message m to process q, then m is infinitely often delivered at q.

No creation:

If some process q delivers some message m from p then process p has previously sent m to q.

#### 2.3.2 Perfect point-to-point links

#### **Events:**

 $\langle sl.send \mid q, m \rangle$  $\langle sl.deliver \mid p, m \rangle$ 

#### **Properties:**

Reliable delivery:

If a correct process sends a message m to a correct process q then q eventually delivers m

No creation:

If process q delivers some m from process p then p has sent m to q

At-most-once delivery:

Every message m is delivered at most once from p to q.

#### 2.3.3 Alg. impl. perfect links (pl) from stubborn links (sl)

```
 \begin{array}{c} \underline{\text{INIT:}} \\ \overline{\mathbb{D}} \leftarrow \emptyset \\ \underline{\text{upon }} \langle pl.send \mid q,m \rangle \, \underline{\text{do}} \\ \underline{\text{trigger }} \langle sl,send \mid q,m \rangle \\ \underline{\text{upon }} \langle sl.deliver \mid p,m \rangle \, \underline{\text{do}} \\ \underline{\text{if }} (p,m) \not\in \mathbb{D} \, \underline{\text{then}} \\ \overline{\mathbb{D}} \leftarrow \mathbb{D} \cup \{(p,m)\} \\ \underline{\text{trigger }} \langle pl.deliver \mid p,m \rangle \\ \end{array}
```

#### 2.4 Timing Assumptions

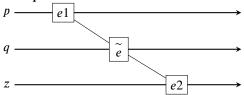

• Asynchronous model (Logical Timing)

If e2 happened after e1 in one process, we know the sequence of events.

If we know that e1 caused e2, we know that e2 happened after e1.

- Three processes

Transitivity holds across processes, so if e1 caused e which cause e2, e2 happened after e1.

• Other time models exist

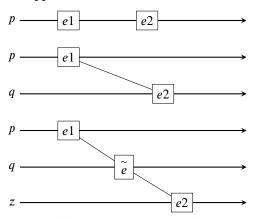

### 3 Timing Assumptions - March 3, 2020

#### 3.1 Asynchronous System

Logical clock creates a logical time

- Each process *p* keeps a logical clock *lp* (initially 0)
- When an event e on p occurs, then  $lp \leftarrow lp + 1$
- When p sends a message m to q, then p attaches a timestamp ts(m) = lp to m
- When p receives a message m' with ts(m'), then p sets  $lp \leftarrow max\{lp, ts(m')\} + 1$

#### 3.1.1 Happens-before relation

In each of these we can say that e1 happens before e2

#### 3.1.2 Lemma

```
e1 occurs at p at lp
e2 occurs at q at lq
\Rightarrow e1 \rightarrow e2, then lp < lq, but not the other way round!
```

#### 3.2 Synchronous System

#### **EITHER:**

- Assume every process has access to a real-time clock (*RTC*)

#### OR:

- Synchronous computation (bounds on computation time)
- Synchonous communication (bounds on message-transmission time)

CAREFUL! when synchrony, assumptions are needed for safety properties

#### 3.3 Partially Synchronous Model

- Synchronous most of the time
- When asynchronous, must not violate safety Formally captured by abstraction of an eventually synchonous system.
- Initial period of asynchrony
- After some point in time (unknown to algorithm), system is synchonous

**NOTE:** Abstract model will remain synchronous forever after sync-point. In practice, periods of synchrony and asynchrony alternate.

#### **3.4** Abstracting Time

**DEFINITION:** Perfect Failure Detecture P

**EVENT:**  $\langle \mathbb{P}.Crash \mid p \rangle$  denotes that process p has crashed.

#### **PROPERTIES:**

#### **STRONG COMPLETENESS:**

Eventually every process that has crashed is detected by all correct processes.

#### STRONG ACCURACY:

For any process p, if p detects that q crashed, then q has crashed.

Formally, all processes are either alive forever or they crash and stop.

Suppose a notion of time in  $\mathbb{N}$ :

 $C: \mathbb{N} \to \Pi$ , C(t) denotes the processes that are live at time t.

 $F: \mathbb{N} \to \Pi$ , F(t) denotes the proceses that are faulty (crashed) at time t.

 $p \in F(t)$ , then  $\forall t' \ge t$ :  $p \in F(t')$  (crashes are irreversible)

 $\mathbb{F} = \bigcup_{t>0} F(t)$ , set of all faulty processes

 $\mathbb{C} = \Pi \setminus \mathbb{F}$ , set of all correct processes

#### Strong Completeness:

 $\exists t : \forall p \in \mathbb{F}, \forall q \in \mathbb{C} : \exists t' \geq t : \langle \mathbb{P}.Crash \mid p \rangle \text{ occurs on process } q \text{ at time } t'.$ 

Strong Accuracy:

 $\forall q \in \mathbb{C} \text{ if } \langle \mathbb{P}.Crash \mid p \rangle \text{ occurs on process } q \text{ at time } t \text{ then } p \in F(t).$ 

#### 3.4.1 Implementing $\mathbb{P}$

```
Initialization: start timer Δ alive ← Π detected ← \emptyset

upon timeout do for all p \in \Pi do

if p \notin alive \land p \notin detected then detected ← detected cup\{p\} start timer with Δ alive ← \emptyset send msg [PING] to all p \in \Pi

upon receive msg. [PING] from p do send msg [PONG] to p

upon receiving [PONG] from p do alive ← alive \cup \{p\}
```

**DEFINITION:** Leader Election

**EVENT:**  $\langle le.leader \mid p \rangle$ , elects p to be leader

**PROPERTIES** (Eventual Leadership):

Eventually, some process l is elected leader by every correct process

#### ACCURACY

If a process is elected leader then all previously elected leaders have crashed.

#### **DEFINITION:** Eventually Perfect Failure Detector

#### **EVENTS:**

 $\langle \diamond \mathbb{P}.Suspect \mid p \rangle$ , process *p* is suspected.

 $\langle \diamond \mathbb{P}.Restore \mid p \rangle$ , process p is thought to be alive.

#### **PROPERTIES**

#### **STRONG COMPLETENESS:**

Eventually, every process that has crashed is suspected by every correct process

#### **EVENTUAL STRONG ACCURACY:**

Eventually, every process that has crashed is suspected permanently by every correct process.

Model	Processes	Timing	
fail-stop	crash-stop	synchronous	$\langle \mathbb{P} \rangle$
fail-noisy	crash-stop	partially synchronous	$\langle \diamond \mathbb{P} \rangle, N > 2F$
fail-silent	crash-stop	asynchronous	N > 2F

### **Distributed Algorithms** LECTURES

### System Models - March 11, 2020

CGR11	processes	timing assumption	assumption	other names
fail-stop	crash	P	-	synchronous
fail-noisy	crash	$\diamond \mathbb{P}, \Omega$	$N > 2\mathbb{F}$	eventually synchronous
fail-silent	crash	-	$N > 2\mathbb{F}$	asynchronous
fail-silent randomized	crash	-	$N > 2\mathbb{F}$ , randomness	asynchronous randomized
fail-revocery	crash-recovery			
fail-arbitrary-noisy	fail-arbitrary	Byz. leader detector	$N > 3\mathbb{F}$	"BFT" (PBFT)
fail-arbitrary-silent -"		-	$N > 3\mathbb{F}$	asynchronous Byzantine
fail-arbitrary randomized	BYZANTINE	-	$N > 3\mathbb{F}$	randomized Byzantine fault model

#### **Chapter 3: Distributed Storage and Shared Memory** 4.1

- Storage abstraction provided by distributed processes
- Here: simplified model where  $\Pi = \mathbb{C}$ , designated processes act as writing/reading clients

#### 4.1.1 Main Abstraction

#### Shared Read-/Write-Register:

```
Operations:
 read() \rightarrow v
 write(v) \rightarrow ACK
```

#### Sequential implementations:

```
state:
    val, initially NULL
   function read()
    return val
   function write(v)
    val \leftarrow v return ACK
Module Register (r):
```

#### Events:

 $\langle r, \text{READ} \rangle$ 

 $\langle r, READRESP \mid v \rangle$ 

 $\langle r, \text{ Write } | v \rangle$ 

 $\langle r, \text{WRITERESP} \rangle$  (acknowledgement)

#### Liveness:

every operation eventually returns a response

#### Safety:

Every read operation returns the value written by the "last write" operation, when no concurrent operation.

## **Distributed Algorithms**LECTURES

#### **Operations:**

every operation modeled by two events

- Invocation event
- Completion event

#### **4.1.2** Definition (Preceding)

Operation  $o_1$  precedes operation  $o_2$  if  $o_1$  completes before  $o_2$  is invoked.

#### **4.1.3** Definition (Sequential)

Operations  $o_1$  and  $o_2$  are sequential if  $o_1$  precedes  $o_2$  or  $o_2$  precedes  $o_1$ .

#### 4.1.4 Definition (Concurrent)

Operations  $o_1$  and  $o_2$  are concurrent if they are not sequential.

#### 4.1.5 Register Example

#### Register Domain

- binary register {0, 1}
- multi-valued register

#### Register Types

- (1,1) 1 writer, 1 reader (SRSW register (single-writer-single-reader))
- (1,N) 1 writer, N readers (MRSW register (multi-writer-single-reader))
- (N,N) N writers, N readers (MRMW register (multi-writer-multi-reader))

#### Semantics:

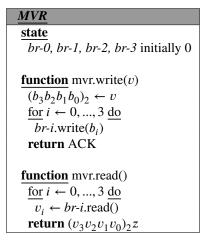

#### Safe:

A read() not concurrent with a write returns the value written by the most recent write() operation (a safe register can return any object from the domain)

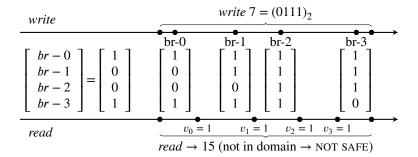

#### 4.1.6 An unsafe register

```
Implement a multi-valued register (mvr) from (many) binary registers. Domain \mathbb{D} = [0, 11] 4 binary registers br - 0, br - 1, br - 2, br - 3 Notation mit function calls: br-0.write(1) mvr.read()
```

**Execution:** initially mvr stores  $9 = (1001)_2$ 

#### Regular Semantics:

Only single-writer registers

Safety:

A read(), not concurrent with a write(), returns the most recently written value.

Otherwise read() returns the most recently written value or the concurrently written values.

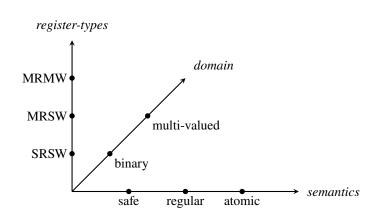

Atomic Semantics: (assume values written are unique)

Safety:

- (1) -"-
- (2) If read()  $\rightarrow v$  and a subsequent read()  $\rightarrow w$ , then write(v) preceds write (w) or write(v) is concurrent to write(w).

Alternative characterization with linearizability

Collaps each operation to its linearization point, which must occur between invocation and response, and values returned satisfy the sequential specifications of the object.

$p_{\perp}$ — write	write(x)		write(u)		
r			•••		
	$read_1$	$read_2$	$read_3$		
	$\downarrow$	$\downarrow$	$\downarrow$		
	x	?	?		
<u>safe</u>	x	any	any		
regular	x	x	x		
		X	и		
		и	$\boldsymbol{x}$		
		и	и		
atomic	x	x	x		
		X	и		
		и	и		

#### 4.1.7 Implementation of an (1,N) Regualar Register in Fail-Silent Mode

### **Majority-Voting** state: val $wts \leftarrow 0$ //writer only **function** rr.write(v) $wts \leftarrow wts + 1$ send message [WRITE, wts, v] to all $p \in \Pi$ wait for message [WRITE-ACK] from > N/2 processors return ACK upon receive message [WRITE, ts', v] from w do $(val, ts) \leftarrow (v, ts')$ send message [WRITE-ACK] to w upon receive message [READ] from r do send message [READVAL, ts, val] to rfunction rr.read() *send* message [READ] to all $p \in \Pi$ wait for message [READVAL, ts', val'] from > N/2 processors let v be the value val' among the received pairs with the highest timestamp return v

### 5 Implementations of Registers - March 18, 2020

### 5.1 REGULAR register implementation in fail-stop model

- synchronous
- Perfect Failure Detector  $\mathbb P$

#### (1,N) regular register (onrr)

```
 \begin{array}{l} \overline{\text{linit:}} \\ val \leftarrow 1 \\ correct \leftarrow \Pi \\ \hline \\ \underline{\text{upon }} \langle onrr\text{-}Write \mid v \rangle \ \underline{\text{do}} \\ \hline \\ \underline{\text{send message }} [\text{WRITE, v}] \ \text{to all } p \in \Pi \text{ //best-effort broadcast} \\ \underline{\text{wait for receiving message }} [\text{ACK] from all processes in } correct \\ \underline{\text{trigger }} \langle onrr\text{-}WriteResponse \rangle \\ \hline \\ \underline{\text{upon receive message }} [\text{WRITE, } v'] \ \text{from process } w \ \underline{\text{do}} \\ \hline \underline{val} \leftarrow v' \\ \text{send message } [\text{ACK] to } w \\ \hline \underline{\text{upon }} \langle \mathbb{P}\text{-}Crash \mid c \rangle \ \underline{\text{do}} \\ \hline \underline{correct} \leftarrow correct \setminus \{c\} \\ \hline \underline{\text{upon }} \langle onrr\text{-}Read \rangle \ \underline{\text{do}} \\ \hline \underline{\text{trigger }} \langle onrr\text{-}Read Return \mid val \rangle \\ \hline \end{array}
```

### 5.2 REGULAR register implementation in fail-silent model

- asynchronous

#### (1,N) regular register with N > 2F

```
(ts, val) \leftarrow (o, \perp)
 wts \leftarrow 0
 rid \leftarrow 0
upon \langle onrr-Write \mid v \rangle do
 wts \leftarrow wts + 1
 send message [WRITE, wts, v] to all p \in \Pi
 wait for receiving message [ACK, ts'] s.t. ts' = wts from > \frac{N}{2} processes
 trigger ⟨onrr-WriteResponse⟩
upon receive message [WRITE, ts', v'] from process w do
 if ts' > ts then
  (ts, val) \leftarrow (ts', v')
 send message [ACK, ts'] to w
upon (onrr-Read) do
 \overline{rid} \leftarrow rid + 1
 send message [READ, rid] to all processes in \Pi
 wait for receive message [VAL, r, ts', v'] s.t. r = rid from > \frac{N}{2} processes
 \overline{v} \leftarrow \text{value } v \text{ in the message with the highest timestamp } ts'
 trigger \langle onrr - ReadReturn \mid \overline{v} \rangle
upon receiving message [READ, r] from process p do
 send message [VAL, r, ts, val] to p
```

#### **5.3** Example execution

#### 5.4 Make Algorithm (ABOVE) (Alg. 4.2) ATOMIC

```
(1,N)-ATOMIC register (onar)
 upon \langle onar - Read \rangle do
  rid \leftarrow rid + 1
   send message [READ, rid] to all processes in \Pi
   wait for receive message [VAL, r, ts', v'] s.t. r = rid from > \frac{N}{2} processes
   (rts, rval) \leftarrow ts', v'-pair from VAL message with highest ts'
   send message [RWRITE, rts, rval] to all p \in \Pi
   wait for receiving message [RACK, rts'] s.t. rts' = rts from > \frac{N}{2} processes
   trigger \(\langle onrr-ReadResponse \) \( rval \rangle \)
 upon receive message [RWRITE, ts', val' from r do
   if ts' > ts then
    (ts, val) \leftarrow (ts', v')
   send message [RACK, ts'] to r
start: (1,N) REGULAR register
intermediate: (1,1) ATOMIC register
goal: (1,N) ATOMIC register
```

#### 5.5 From (1,1) ATOMIC to (1,N) ATOMIC register

tikz

#### **Transformation:**

```
implements: (1,N) ATOMIC register (onar)
uses: (1,1) ATOMIC register (u^2 : ooar.i.j)
 Init: ts \leftarrow 0
 operation onar-WRITE(v) is
   ts \leftarrow ts + 1
   for p \in \Pi do
    ooar.p.w-WRITE((ts, v))
   return ACK
  operation onar-READ() is
   readList ← []
   for p \in \Pi do
    readList[p] \leftarrow ooar.self.p-READ()
   (maxts, maxval) \leftarrow highest(readList)
   \underline{\text{for }} p \in \Pi \underline{\text{do}}
    ooar.p.self-WRITE((maxts, maxval))
   return maxval
```

### 5.6 From (1,N) ATOMIC to (N,N) ATOMIC register

tikz

- writer uses highest timestamp that it reads
- timestamps become (ts, index) duples (index of process)

### 5.7 Register Implementation in BYZANTINE Model (N > 3F)

tikz01 tikz02

- relax the specification
- introduce data authentication using digital signature

### 6 Byzantine Distributed Storage - March 25, 2020

#### 6.1 Specification

tikz

```
6.1.1 (1, N)-REGULAR Register
```

```
IN: \langle Read \rangle OUT: \langle ReadReturn \mid v \rangle IN: \langle Wirte \mid v \rangle OUT: \langle WriteReturn \rangle
```

#### - Termination:

Every operation eventually terminates

- Validity:

every *read* returns either <u>the</u> concurrently written value or the most recently written value

```
\frac{\underline{\text{Init:}}}{(ts, val, sig)} \leftarrow (\bot, \bot, \bot)
wts \leftarrow 0
```

```
\frac{\text{upon } write(v) \text{ do}}{wts \leftarrow wts + 1}
\sigma \leftarrow sign(\text{WRITE} || wts || v)
```

send message [WRITE, wts, v,  $\sigma$ ] to all processes wait for messages [ACK, ts'] s.t. ts' = wts from  $> \frac{n+f}{2}$  processes (BYZANTINE quorum)

```
upon receive message [WRITE, ts', v', \sigma'] do

\underline{if} ts' > ts \underline{then} \\
(ts, val, \sigma) \leftarrow (ts', v', \sigma')
```

```
(ts, val, \sigma) \leftarrow (ts', v', \sigma')
send message [ACK, ts'] to writer w
```

```
upon read() do
```

send message [READ] to all processes <u>wait for message [VALUE, ts', v',  $\sigma'$ ] from  $> \frac{n+f}{2}$  with  $verifySign(\sigma', WRITE <math>||ts'||v') = TRUE$  let v be the received value v' from message with the highest timestamp ts'</u>

return v

upon [READ] ...

- Termination

*n* replicas and *f* faulty  $\Rightarrow \ge n - f$  responses Show:  $n - f > \frac{n+f}{2}$ , if n > 3f

$$n-f > \frac{n+f}{2}$$
, if  $n > 3f$  ...

- Validity:

tikz

- Safety:

 $Q_w$  quorum used by writer

 $Q_r$  quorum used by reader

$$|Q_w| > \frac{n+f}{2}$$

$$|Q_r| > \frac{n+f}{2}$$

Show: There exists at least one correct process in  $Q_w \cap Q_r$  Suppose not:

Count number of distinct correct processes in  $Q_w \cap Q_r$ 

number is 
$$\geq |Q_w| - f + |Q_r| - f > \frac{n+f}{2} - f + \frac{n-f}{2} - f = n - f$$
  
 $\Rightarrow$  So there exists at least one correct process in  $Q_w \cap Q_r$ 

#### 6.1.2 Can we implement this w/o signatures?

tikz

- could return c default value
- this idea can be turned into for emulating  $< \underline{\text{safe}}$  BYZANTINE registers assuming n > 4f processes
- (2-round protocol with n > 3f exists...)

#### 6.1.3 Practical Leaderless Replication

- clients send request directly to replicas
- possibly via some coordinator
- tikz
- Consistency of the stored data
  - auxiliaty service within storage system will eliminate differences "anti-entropy"
  - read-repair by reading clients that detect inconsistent clients
- Quorums for reading and writing

r - replicas for reading

w - replicas for writing

so far:  $r = w > \frac{n}{2}$ 

r = 1, w = n read-one write-all

r = n, w = 1 read-all write-one

- Strong Consistency iff r + w > n

Some systems use  $r + w \le n$ 

### 6.2 Key-Value Store (KVS)

- Replica set usually differs for each pair
- Semantics is not formally specified
  - ... too expensive
  - ... atomic problematic because the reader would write
- Conflicts?
  - resolved using heuristic methods
  - last-write wins policy
    - ... data loss is possible
- Practical system ensure usually a notion of eventual consistency
- Some systems let clients merge conflicting written values
  - often easy for applications
  - very difficult in general
  - ... AMAZON Dynamo tikz

### 7 CHAPTER 4: Reliable Broadcast - April 01, 2020

#### 7.1 Definition

(IN)  $\langle BROADCAST \mid m \rangle$  "broadcast a message m" (OUT)  $\langle DELIVER \mid p, m \rangle$  "delivers a message m from sender p"

tikz

#### 7.2 Best-Effort Broadcast (UNRELIABLE)

#### **7.2.1 Definition (VALIDITY):**

If a *correct* process broadcasts a message m, then every *correct* process eventuall delivers m.

#### 7.2.2 Definition (NO DUPLICATION):

No message is delivered more than once.

#### 7.2.3 Definition (NO CREATION):

If a process delivers a message m with sender s, then m was previously broadcasted by process s.

#### 7.3 Messages are UNIQUE

How do we ensure this in practice? . . .

#### 7.4 Reliable Broadcast

#### 7.4.1 Definition:

Same properties as (unreliable) best-effort broadcast.

#### Agreement

If a message *m* is delivered by a *correct* process then every *correct* process eventually delivers *m*.

#### 7.5 EAGER Reliable Broadcast

Init:  $delivered \leftarrow \emptyset$ upon  $\langle rb\text{-}\mathsf{BROADCAST} \mid m \rangle \underline{do}$ send message [DATA, self, m] to all  $p \in \Pi$ upon receive message [DATA, s, m] from  $q \underline{do}$ if  $m \notin delivered \underline{then}$   $delivered \cup \leftarrow \{m\}$ send message [DATA, s, m] to all  $p \in \Pi$ trigger  $\langle rb\text{-}\mathsf{DELIVER} \mid s, m \rangle$ 

#### 7.5.1 Implementation:

tikz

#### A process that crashes:

All modules crash simultaneously.

#### 7.5.2 How adequate is this (basic) reliable broadcast?

tikz

#### 7.6 UNIFORM Reliable Broadcast

#### 7.6.1 Definition:

Same properties as regular reliable broadcast.

#### **Uniform Agreement:**

If a process delivers a message m, then every correct process eventually delivers m.

#### **7.6.2** Implementation of URB in async. netw. with f crashes and N > 2f

```
\begin{aligned} &pending \leftarrow \emptyset \\ &ack[] \leftarrow [] \\ &delivered \leftarrow \emptyset \\ &upon \ \langle urb\text{-}\mathsf{BROADCAST} \mid m \rangle \ \underline{do} \\ &pending \cup \leftarrow \{(self,m)\} \\ &send \ \mathrm{message} \ [\mathsf{DATA}, self, m] \ \mathrm{to} \ \mathrm{all} \ p \in \Pi \end{aligned} &\underbrace{upon \ receive \ message} \ [\mathsf{DATA}, s, m] \ \mathrm{from} \ q \ \underline{do} \\ &\underline{ack[m]} \leftarrow ack[m] \cup \{q\} \\ &\underline{if} \ (s,m) \not\in pending \ \underline{then} \\ &pending \leftarrow \{(s,m)\} \\ &send \ \mathrm{message} \ [\mathsf{DATA}, s, m] \ \mathrm{to} \ \mathrm{all} \ p \in \Pi \end{aligned} &\underbrace{upon \ \exists (s,m) \in pending \&\&m \not\in delivered \ s.t. \ | \ ack[m] \ | > \frac{N}{2} \ \underline{do} \\ &\underline{delivered} \cup \leftarrow \{m\} \\ &trigger \ \langle urb\text{-}\mathsf{DELIVER} \ | \ s,m \rangle \end{aligned}
```

- If q delivers m, then it has received the DATA messages from  $> \frac{N}{2}$  processes
- Since  $f < \frac{n}{2}$ , at least one DATA message was sent by a correct process, this process has sent m ro all other processes
- All correct processes eventually send DATA message containing m
- all correct processes eventually deliver m

#### 7.7 Order

tikz

#### 7.7.1 FIFO-Order Broadcast

per-sender order

#### **Interface**

Same as reliable broadcast

#### **Properties**

- Validity
- No Duplication
- No creation
- Agreement
- FIFO-Order (if bc.  $m_1 \rightarrow m_2$  then del.  $m_1 \rightarrow m_2$ ) If process broadcasts  $m_1$  and subsequently broadcasts  $m_2$ , then no process delivers  $m_2$  unless it has also delivered  $m_1$  before.

#### **Implementation**

- Each process adds a (local) sequence number to every payload message
- For each sender, every receiver delivers payload messages according to the sequence number (requiring buffering)

#### 7.7.2 Causal Order (broadcast):

tikz

#### Prevent such violations of causal order:

- keep track of complete history of past delivered messages

## **Distributed Algorithms**LECTURES

#### 8 CHAPTER 6: Total-Order Broadcast - 08.04.2020

#### 8.1 Notion of Causality

#### **8.1.1** Events

- BROADCAST(m)
- DELIVER(m)

#### 8.1.2 Causality Relation

 $m_1 \rightarrow m_2$ 

when one of the 3 conditions apply:

- 1. process p broadcasts  $m_1$  before it broadcasts  $m_2$
- 2. some process delivers  $m_1$  and later broadcasts  $m_2$
- 3. some message  $m_3$  exists s.t.  $m_1 \rightarrow m_3$  and  $m_3 \rightarrow m_2$

#### 8.2 Causal-Order Broadcast using Vector Clocks

$$\frac{\text{Init:}}{V \leftarrow [0]^n}$$

$$lsn \leftarrow 0$$

$$pending \leftarrow \emptyset$$

$$\frac{\text{upon } \langle crb - \text{BROADCAST} \mid m \rangle \underline{\text{do}}}{w \leftarrow V \quad V[rank(self)] \leftarrow lsn}$$
$$lsn \leftarrow lsn + 1$$
$$\underline{\text{trigger } \langle rb - \text{BROADCAST} \mid [W, m] \rangle}$$

$$\frac{\text{upon } \langle rb - \text{Deliver } | p, [W, m] \rangle \text{ do}}{pending \leftarrow pending \cup \{[W, m]\}}$$

$$\underline{\text{if } \exists (\overline{p}, \overline{W}, \overline{m} \in pending \wedge \overline{W} \leq V \text{ then}}{pending \leftarrow pending \setminus \{[\overline{p}, \overline{W}, \overline{m}]\}}$$

$$V[rank(\overline{p})] \leftarrow V[rank(\overline{p})] + 1$$

$$\text{trigger } \langle crb - \text{Deliver } | \overline{p}, \overline{m} \rangle$$

#### **8.2.1** Example

tikz

#### 8.3 Total-Order Broadcast

 $\dots$  is a reliable broadcast with the following additional total-order property:

For two messages  $m_1$  and  $m_2$  such that processes p and q have both delivered  $m_1$  and  $m_2$ , then p delivers  $m_1$  before  $m_2$  iff q delivers  $m_1$  before  $m_2$ . Any delivery sequence of a process is a prefix of another process which has more messages delivered.

#### 8.4 Consensus

#### **8.4.1** Events

```
(IN) \langle c - \text{PROPOSE} \mid v \rangle - ... proposes v ... (OUT) \langle c - \text{DECIDE} \mid v \rangle - ... decides for v ...
```

#### 8.4.2 Properties

#### **Termination:**

Every correct process eventually decides some value.

#### Validity:

If a process decides a value v, then v was proposed by some process

#### **Integrity:**

A process decides at most once.

#### **Agreement:**

No two (correct) processes decide different values.

## **Distributed Algorithms**LECTURES

#### 8.5 From Consensus to Total-Order Broadcast

```
Init:
 unordered \leftarrow \emptyset
 delivered \leftarrow \emptyset
 r \leftarrow 1
 wait ← FALSE ... consensus is running?
upon \langle tob - BROADCAST \mid m \rangle do
 trigger \langle rb - BROADCAST \mid m \rangle
upon \langle rb - \text{Deliver} \mid p, m \rangle \underline{\text{do}}
 if m \notin delivered then
   unordered \leftarrow unordered \cup \{(p, m)\}
upon unordered \neq \emptyset \land \neg wait do
 wait \leftarrow \texttt{TRUE}
 initialise consensus instance c.r
 trigger \langle c.r - PROPOSE \mid unordered \rangle
upon \langle c.r - \text{DECIDE} \mid d \rangle \underline{\text{do}}
 for (s, m) \in d in some fixed order do
   trigger \langle tob - DELIVER \mid s, m \rangle
   delivered \leftarrow delivered \cup \{m\}
   unordered \leftarrow unordered \setminus \{(s, m)\}
 r \leftarrow r + 1
 wait \leftarrow FALSE
```

#### 8.6 From Total-Order Broadcast to Consensus

tikz

#### 8.7 State-Machine Replication

tikz

#### **8.7.1** Events

```
(IN) \langle rsm - \text{EXECUTE} \mid command \rangle - ... proposes v ... (OUT) \langle rsm - \text{OUTPUT} \mid response \rangle - ... decides for v ...
```

#### 8.7.2 Properties

#### **Termination:**

If a correct process executes a command, then the process eventually also outputs a response (for that command).

#### **Agreement:**

All correct processes output the same sequence of responses

### 8.8 From Total-Order Broadcast to Replicated State-Machine

Init:
$$\underline{\text{state}} \leftarrow \bot$$

$$\underline{\text{upon}} \langle rsm - \text{EXECUTE} \mid cmd \rangle \underline{\text{do}}$$

$$\underline{\text{trigger}} \langle tob - \text{BROADCAST} \mid cmd \rangle$$

$$\underline{\text{upon}} \langle tob - \text{DELIVER} \mid p, cmd \rangle \underline{\text{do}}$$

$$\overline{(r, state)} \leftarrow F(cmd, state)$$

$$\underline{\text{trigger}} \langle rsm - \text{OUTPUT} \mid r \rangle$$

### 9 CONSENSUS - April 22, 2020

#### 9.1 Definition

#### **9.1.1** Events

```
(IN) propose (v) (OUT) decide (v)
```

#### 9.1.2 Properties

- Termination:
  - ... terminates
- Validity:

decision value v was proposed

- Integrity:

decide at most once

- Agreement:

No two processes decide different values

### 9.2 Flooding Uniform CONSENSUS

```
init:
 correct \leftarrow \Pi
 round \leftarrow 1
 decision \leftarrow \bot
 proposals \leftarrow \{\}
upon uc- PROPOSE(v) do
 proposals \leftarrow proposals \cup \{v\}
 trigger \langle beb-BROADCAST | [PROP, 1, proposals]\rangle
upon \langle \mathbb{P} - \text{CRASH} \mid p \rangle \underline{\text{do}}
 correct \leftarrow correct \setminus \{p\}
upon \langle beb-DELIVER | p, [PROP, r, ps] \rangle such that r = round do
 received \leftarrow received \cup \{p\}
 proposals \leftarrow proposals \cup ps
upon correct \subseteq received do
 if round < N then
   round \leftarrow round + 1
   received \leftarrow \emptyset
   trigger \langle beb-BROADCAST | [PROP, round, proposals] \rangle
                                                                                       // round = N
 else
   decision \leftarrow min(proposals)
  DECIDE(decision)
```

## **Distributed Algorithms**LECTURES

#### 9.3 Consensus Protocol with Eventual Synchrony

- Consensus mechanism inside Paxos, Viewstamp Replication, ZooKeeper, Raff
- more complex than the *fail-stop* protocol (with  $\mathbb{P}$ ) because it uses  $\Omega$  ( $\diamond \mathbb{P}$ )

#### \* Leader-Driven CONSENSUS

tikz

- every epoch has a leader

#### 9.3.1 Epoch-Change

**Event:**  $\langle ec\text{-}Start\ Epoch \mid ts,\ l$ 

#### **Properties:**

Monotonicity:

If a process start epoch (ts, l) and subsequently start epoch (ts', l'), then ts' > ts

Consistency:

If a process starts epoch (ts, l) and also another process starts epoch (ts', l') and ts = ts' then l = l'

Leadership:

- There is a last epoch that is started at every process
- the leader of this last epoch is correct

#### 9.3.2 Epoch-Consensus

#### **Events:**

```
IN \langle ep\text{-Propose} \mid v \rangle // only leader OUT \langle ep\text{-Decide} \mid v \rangle IN \langle ep\text{-Abort} \rangle OUT \langle ep\text{-Aborted} \mid state \rangle
```

#### **Properties:**

*Validity:* 

If a process ep-DECIDES v, then v was ep-PROPOSED (by the leader) in some epoch  $ts' \le ts$ 

Agreement:

(as before)

Integrity:

(as before)

Termination:

If the leader l of epoch ts is correct, and w process aborts, then every correct process eventually ep-DECIDES

Lock-In:

If a process has ep-DECIDED v in epoch ts' < ts, then w

Abort Completeness: ...

#### 9.4 Leader-Driven Consensus

```
Init:
 val \leftarrow \bot
 proposed \leftarrow F
 decided \leftarrow F
 Init ep-Consensus with (0, l_0) [ep.0]
 (ets, l) \leftarrow (0, l_0)
upon \langle uc-Propose |v\rangle do
 val \leftarrow v
upon \langle ec	ext{-STARTEPOCH} \mid nts, nl \rangle \underline{do}
 (newts, newl) \leftarrow (nts, nl)
 abort the current epoch (ets, l) ...
upon ⟨ep.ts-ABORTED | state⟩
 (ets, l) \leftarrow (newts, newl)
 Initialize ep-Consensus with state and (ets, l)
upon val \neq \bot \land l = self \land proposed = F \underline{do}
 proposed \leftarrow T
 trigger \( \left( ep.ets-\text{PROPOSE} \ | val \rangle \)
upon \langle ep.ts-DECIDE | v \rangle such that ts = ets do
 if \neq decided then
   decided \leftarrow T
   trigger \langle uc\text{-DECIDE} \mid v \rangle
```

#### 9.4.1 Why Agreement?

- if in same epoch, then ep-CONSENSUS agreement property
- otherwise, locking property ensures agreement

### 10 10th Lecture - April 29, 2020

10.1 sub

10.1.1 subsub

### 11 Byzantine Consensus - May 6, 2020

#### 11.1 Weak Byzantine Consensus

#### 11.1.1 Events

- propose(v)
- decide(v)

#### 11.1.2 Properties

#### - Termination

Eventually correct process eventually decides

#### - Weak Validity

If all processes are correct, and all propose v, then no correct process decides a value different from v; if all processes are correct, and some correct process decides v, then v was proposed by some process.

#### - Agreement

No two correct processes decide on different values

#### 11.2 Strong Byzantine Consensus

Same as waek Byzantine consensus, but with...

#### 11.2.1 Properties

#### - Strong Validity

If all correct processes propose the same value v, then every correct process decides v; otherwise, a correct process must decide a special value  $\square$  (blank), or a value proposed by a correct process.

#### 11.3 Special Case: Binary Consensus

#### 11.3.1 Properties

#### - Strong Validity

The decision value was proposed by a correct process.

Simplification because there are only two decision values.

#### 11.4 Fault-Tolerance

Byzantine Consensus requires a strong majority of correct processes.

#### 11.4.1 Theorem

Every strong Byzantine Consensus protocol tolerates at most  $f < \frac{N}{3}$  faulty processes.

#### 11.4.2 **Proof**

Suppose not.

Consider f = 1. Then there is a Byzantine consensus protocol for N = 3 processes.

**Execution A** 

tikz

**Execution B** 

tikz

**Execution C** 

tikz

One can extend this argument to N > 3 processes, as long as  $N \le 3f$ .

#### 11.4.3 Intuition

- processes can wait for at most N f others
- among these N f, a majority must be correct

#### 11.5 Reliable Broadcasts with Byzantine Faults

#### 11.5.1 Events

- broadcast(m)
- deliver(*m*)

Byzantine broadcasts (here) can broadcast and deliver one payload message; with identified sender *s* (to broadcast multiple payloads, run many such protocols in parallel).

#### 11.5.2 Properties

- Validity

If a correct sneder s broadcasts m, then every correct process eventually delivers m

- No Duplication
- Integrity
- Consistency

If a correct process delivers m, and another correct process delivers m', then m = m'.

#### 11.6 Signed Echo Broadcast

```
tikz
```

$$\begin{array}{l} \underline{\operatorname{Init:}} \quad sentecho \leftarrow F \\ \overline{sentfinal} \leftarrow F \\ \\ \underline{\operatorname{upon}} \quad cb\text{-}broadcast(n) \; \underline{\operatorname{do}} \\ \overline{\operatorname{send}} \quad \operatorname{messgae} \; [\operatorname{SEND}, m] \; \operatorname{to} \; \operatorname{all} \; \operatorname{processes} \\ \\ \underline{\operatorname{upon}} \quad \operatorname{receiving} \; \operatorname{message} \; [\operatorname{SEND}, m] \; \operatorname{from} \; s \; \operatorname{and} \; \neq sentecho \; \underline{\operatorname{do}} \\ \overline{\sigma} \leftarrow sign(\operatorname{ECHO} \| identifier\| m) \\ \operatorname{send} \; \operatorname{message} \; [\operatorname{ECHO}, m, \sigma'] \; \operatorname{from} \; > \; \frac{N+f}{2} \; \operatorname{distinct} \; \operatorname{processes} \; \operatorname{and} \; \neg sentfinal \; \underline{\operatorname{do}} \\ \Sigma \leftarrow \text{ list of received sig. } \; \sigma \\ \operatorname{send} \; \operatorname{message} \; [\operatorname{FINAL}, m, \Sigma] \\ sentfinal \leftarrow T \\ \end{array}$$

upon receive message [FINAL, m,  $\Sigma$ ] do

if verify that  $\Sigma$  contains  $> \frac{N+f}{2}$  signatures on ECHO ||identifier||m| then deliver(m)

#### 11.6.1 Why Consistent?

```
some p has delivered m, then it has > \frac{N+f}{2} sig. on m some p' has delivered m', then it has > \frac{N+f}{2} sig. on m' how many distinct correct processes have signed? p has seen > \frac{N-f}{2} signatures (on m) from correct processes p' has seen > \frac{N-f}{2} signatures (on m') from correct processes. This means, p and p' have together seen > N-f signatures from correct processes. But there are only N-f correct processes \Rightarrow m=m'
```

This protocol uses signatures.

An alternative protocol uses pt-to-pt messages, where signatures are replaced by messages:

tikz

#### 11.7 Byzantine Reliable Broadcasts (BRACHA)

#### 11.7.1 Definition

A protocol for Byzantine Reliable Broadcast is a Byzantine consistent broadcast that satisfies also:

#### - Totality

If a correct process delivers some message, then every correct process eventually delivers some message.

Totality + Consistency = Reliability

#### 11.7.2 Implementation (by BRACHA)

Authenticator Double-Echo Broadcast

tikz

- All correct processes sned [READY, m] upon receiving >  $\frac{N+f}{2}$  ECHO messages with m
- All correct processes also send [READY, m] after receiving > f READY messages with m
- $\Rightarrow$  and a correct process delivers m upon receiving > 2f messages [READY, m]

#### 11.7.3 Why does this ensure totality?

Suppose p that has delivered m

- $\Rightarrow$  p has received more than 2f READY messages with m
- $\Rightarrow$  more than f READY messages from correct processes
- $\Rightarrow$  every correct process eventually receives > f READY messages with m
- $\Rightarrow$  every correct process eventually sends READY with m
- $\Rightarrow$  every correct process eventually receives > 2f READY, because N-f>2f assuming that N>3f

#### 11.7.4 How can we croadcast many payload messages?

- Run one instance of basic broadcast for each process as a sender
- After one instance delivers a message m, just start another one
- $\Rightarrow$  Byzantine  $\{\substack{Reliable \\ Consistent}\}$  Broadcast Channel

#### 11.8 Byzantine Total Order Broadcasts

- Analogous to model with crash failures
- In principle, implement from one consensus instance for each round, as before
- In practice, more complex protocols are used which are efficient.

### 12 12th Lecture - May 6, 2020

12.1 sub

12.1.1 subsub
